

CLINICAL GUIDELINES FOR Postoperative Nutrition Management

Over 90% of dog owners are worried about occurrence of gastrointestinal upset after surgery and are willing to start a proactive management plan recommended by their veterinarian.¹

From beginning to end, each step of your surgical protocol can influence development of postoperative nausea, vomiting, and intestinal dysbiosis and this impact needs to be considered for comprehensive patient management.

- **Fasting:** Fasting pets for as little as 12 hours has been shown to have a significant, negative impact on gastrointestinal tract motility.²
- **Pre-medication:** Many pain medications, particularly opioids, can produce mild to severe gastrointestinal side effects including nausea, vomiting, diarrhea, decreased appetite, and ileus.³

- **General anesthesia:** Up to 33% of dogs experience perioperative or postoperative GI side effects associated with general anesthesia.⁴
- **Antibiotics:** Peri and postoperative antibiotic use in dogs has been shown to induce intestinal dysbiosis that may not fully resolve even 3 months post-surgery.⁵

Proactively implementing a postoperative feeding plan, even for routine procedures including spays, neuters, or dental prophylaxis, focused on high digestibility and microbiome support helps improve wound healing and promote gastrointestinal recovery after surgery.⁶

- Great-tasting, highly digestible nutrition clinically proven to help resolve diarrhea and support recovery.
- Fortified with ActivBiome+ Digestion, a proprietary blend of prebiotic fibers clinically shown to rapidly activate the gut microbiome to support digestive health.
